Solutions to Problems in Chapter One

1.1 $W = mg = 3(32.2) = 96.6 \text{ lb.}$

1.2 $m = W / g = 100 / 9.81 = 10.19 \text{ kg.}$ $W = 100(0.2248) = 22.48 \text{ lb.}$
 $m = 10.19(0.06852) = 0.698 \text{ slug.}$

1.3 $d = (50 + 5 / 12)(0.3048) = 15.37 \text{ m.}$

1.4 $d = 3(100)(0.3048) = 91.44 \text{ m}$

1.5 $d = 100(3.281) = 328.1 \text{ ft}$

1.6 $d = 50(3600) / 5280 = 34.0909 \text{ mph}$

1.7 $v = 100(0.6214) = 62.14 \text{ mph}$

1.8 $n = 1 / \left[60(1.341 \times 10^{-3}) \right] = 12.43$, or approximately 12 bulbs.

1.9 $5(70 - 32) / 9 = 21.1^\circ \text{ C}$

1.10 $9(30) / 5 + 32 = 86^\circ \text{ F}$

1.11 $\omega = 3000(2\pi) / 60 = 314.16 \text{ rad/sec.}$ Period $P = 2\pi / \omega = 60 / 3000 = 1 / 50 \text{ sec.}$

1.12 $\omega = 5 \text{ rad/sec.}$ Period $P = 2\pi / \omega = 2\pi / 5 = 1.257 \text{ sec.}$ Frequency $f = 1 / P = 5 / 2\pi = 0.796 \text{ Hz.}$

1.13 Speed $= 40(5280) / 3600 = 58.6667 \text{ ft/sec.}$ Frequency $= 58.6667 / 30 = 1.9556 \text{ times per second.}$

1.14 $x = 0.005 \sin 6t$, $\dot{x} = 0.005(6) \cos 6t = 0.03 \cos 6t$. Velocity amplitude is 0.03 m/s. $\ddot{x} = -6(0.03) \sin 6t = -0.18 \sin 6t$. Acceleration amplitude is 0.18 m/s². Displacement, velocity and acceleration all have the same frequency.

1.15 Physical considerations require the model to pass through the origin, so we seek a model of the form $f = kx$. A plot of the data shows that a good line drawn by eye is given by $f = 0.2x$. So we estimate k to be 0.2 lb/in.

1.16 The script file is

```
x = [0:0.01:1];
subplot(2,2,1)
plot(x,sin(x),x,x,xlabel('x (radians)'),ylabel('x and sin(x)'),...
gtext('x'),gtext('sin(x)')
subplot(2,2,2)
plot(x,sin(x)-x,xlabel('x (radians)'),ylabel('Error: sin(x) - x')
subplot(2,2,3)
plot(x,100*(sin(x)-x)./sin(x)),xlabel('x (radians)'),...
ylabel('Percent Error'),grid
```

The plots are shown in the figure.

Figure : for Problem 1.16.

From the third plot we can see that the approximation $\sin x \approx x$ is accurate to within 5% if $|x| \leq 0.5$ radians.

1.17 For θ near $\pi/4$,

$$f(\theta) \approx \sin \frac{\pi}{4} + \left(\cos \frac{\pi}{4} \right) \left(\theta - \frac{\pi}{4} \right)$$

For θ near $3\pi/4$,

$$f(\theta) \approx \sin \frac{3\pi}{4} + \left(\cos \frac{3\pi}{4} \right) \left(\theta - \frac{3\pi}{4} \right)$$

1.18 For θ near $\pi/3$,

$$f(\theta) \approx \cos \frac{\pi}{3} - \left(\sin \frac{\pi}{3} \right) \left(\theta - \frac{\pi}{3} \right)$$

For θ near $2\pi/3$,

$$f(\theta) \approx \cos \frac{2\pi}{3} - \left(\sin \frac{2\pi}{3} \right) \left(\theta - \frac{2\pi}{3} \right)$$

1.19 For h near 25,

$$f(h) \approx \sqrt{25} + \frac{1}{2\sqrt{25}}(h-25) = 5 + \frac{1}{10}(h-25)$$

1.20 For r near 5,

$$f(r) \approx 5^2 + 2(5)(r-5) = 25 + 10(r-5)$$

For r near 10,

$$f(r) \approx 10^2 + 2(10)(r-10) = 100 + 20(r-10)$$

1.21 For h near 16,

$$f(h) \approx \sqrt{16} + \frac{1}{2\sqrt{16}}(h-16) = 4 + \frac{1}{8}(h-16)$$

and $f(h) \geq 0$ if $h > -16$.

1.22 Construct a straight line that passes through the two endpoints at $p = 0$ and $p = 900$. At $p = 0$, $f(0) = 0$. At $p = 900$, $f(900) = 0.002\sqrt{900} = 0.06$. This straight line is

$$f(p) = \frac{0.06}{900}p = \frac{1}{15,000}p$$

1.23 a)

$$4 \int_2^x dx = 3 \int_0^t t dt$$

$$x(t) = 2 + \frac{3}{8} t^2$$

b)

$$5 \int_3^x dx = 2 \int_0^t e^{-4t} dt$$

$$x(t) = 3.1 - 0.1 e^{-4t}$$

c) Let $v = \dot{x}$.

$$3 \int_7^v dv = 5 \int_0^t t dt$$

$$v(t) = \frac{dx}{dt} = 7 + \frac{5}{6} t^2$$

$$\int_2^x dx = \int_0^t \left(7 + \frac{5}{6} t^2 \right) dt$$

$$x(t) = 2 + 7t + \frac{5}{18} t^3$$

d) Let $v = \dot{x}$.

$$4 \int_2^v dv = 7 \int_0^t e^{-2t} dt$$

$$v(t) = \frac{23}{8} - \frac{7}{8} e^{-2t}$$

$$\int_4^x dx = \int_0^t \left(\frac{23}{8} - \frac{7}{8} e^{-2t} \right) dt$$

$$x(t) = \frac{57}{16} + \frac{23}{8} t + \frac{7}{16} e^{-2t}$$

e) $\dot{x} = C_1$, but $\ddot{x}(0) = 5$, so $C_1 = 5$. $x = 5t + C_2$, but $x(0) = 2$, so $C_2 = 2$. Thus $x = 5t + 2$.

1.24 From (1.4.4),

$$\alpha = \frac{(10)^2}{2(2)(1000)} = 0.025$$

$$f = (\alpha + 1)mg = 1.025(5000)(2) = 10,250 \text{ N}$$

From (1.4.2),

$$t_f = \frac{v_0}{\alpha g} = \frac{10}{0.025(2)} = 200 \text{ s}$$

1.25 Let $\dot{h}(0) = b = -v_0$.

$$\dot{h}(t_f) = 0 = at_f - v_0$$

so

$$a = \frac{v_0}{t_f}$$

Thus

$$h(t) = \frac{a}{2}t^2 - v_0t + h_0 = \frac{v_0}{2t_f}t^2 - v_0t + h_0$$

and

$$h(t_f) = \frac{v_0}{2t_f}t_f^2 - v_0t_f + h_0 = 0$$

which gives

$$t_f = \frac{2h_0}{v_0}$$

and

$$a = -\frac{v_0}{t_f} = \frac{v_0^2}{2h_0}$$

Also, since $\ddot{h} = a$,

$$f = m(\ddot{h} + g) = m(a + g) = m\left(\frac{v_0^2}{2h_0} + g\right)$$

1.26 We require that $\dot{h}(t_f) = -v_f$. From (1.4.3),

$$h(t) = \alpha g \frac{t^2}{2} - v_0 t + h_0$$

$$\dot{h} = \alpha g t - v_0$$

$$\dot{h}(t_f) = \alpha g t_f - v_0 = -v_f$$

so

$$t_f = \frac{v_0 - v_f}{\alpha g} = (v_0 - v_f) \frac{2h_0}{v_0^2}$$

Equation (1.4.4) stays the same, so the thrust stays the same as (1.4.6):

$$f = (\alpha + 1)mg$$

1.27 a.

$$f = m(\ddot{h} + g) = m(2at + b + g)$$

Find a and b .

$$\dot{h}(t_f) = at_f^2 + bt_f - v_0 = 0 \quad (1)$$

$$h(t) = \frac{a}{3}t^3 + \frac{b}{2}t^2 - v_0t + h_0$$

and

$$h(t) = \frac{a}{3}t_f^3 + \frac{b}{2}t_f^2 - v_0t_f + h_0 = 0 \quad (2)$$

Solve (1) and (2) for a and b :

$$a = \frac{6h_0 - 3v_0t_f}{t_f^3}$$

$$b = \frac{4v_0}{t_f} - \frac{6h_0}{t_f^2}$$

Thus t_f is free to be chosen.

b. 1.

$$a = \frac{6(500) - 3(5)(200)}{(200)^3} = 0$$

$$b = \frac{4(5)}{200} - \frac{6(500)}{(200)^2} = 0.025$$

$$f = 5062.5$$

2.

$$a = \frac{6(500) - 3(5)(100)}{(100)^3} = 0.0015$$

$$b = \frac{4(5)}{100} - \frac{6(500)}{(100)^2} = -0.1$$

$$f = 2500(0.003t + 1.9) = 7.5t = 4750$$

1.28 The total inertia is $I = I_m + I_s + I_L = 0.005 + 0.002 + 0.008 = 0.015$. From Figure 1.5.4 we obtain the required angular acceleration from the slope of the velocity curve. This gives

$$\dot{\omega} = \begin{cases} \frac{200}{0.1} = 2000 & 0 \leq t \leq 0.1 \\ 0 & 0.1 < t < 4.5 \\ -\frac{200}{0.1} = -2000 & 4.5 \leq t \leq 4.6 \end{cases}$$

Thus the required torque is

$$T = I\dot{\omega} = \begin{cases} 30 & 0 \leq t \leq 0.1 \\ 0 & 0.1 < t < 4.5 \\ -30 & 4.5 \leq t \leq 4.6 \end{cases}$$

So the maximum required torque is 30 N·m.

The rms average torque is calculated as follows:

$$T_{rms} = \sqrt{\frac{1}{4.6} [(30)^2 (0.1) + (0)^2 (4.4) + (-30)^2 (0.1)]} = 6.255 \text{ N} \cdot \text{m}$$

1.29 The equation of motion is now

$$I\dot{\omega} = T - T_f \quad \omega > 0$$

Thus

$$T = I\dot{\omega} + T_f = \begin{cases} 30 + 3 = 33 & 0 \leq t \leq 0.1 \\ 3 & 0.1 < t < 4.5 \\ -30 + 3 = -27 & 4.5 \leq t \leq 4.6 \end{cases}$$

So the maximum required torque is 33 and the rms torque is

$$T_{rms} = \sqrt{\frac{1}{4.6} [(33)^2 (0.1) + (3)^2 (4.4) + (-27)^2 (0.1)]} = 6.938 \text{ N} \cdot \text{m}$$

1.30 The total load displacement is given as $\theta_f = 10\pi$ rad. We also have $t_f = 0.5$ s and a slew time of $t_2 - t_1 = 0.4$ s. Using a symmetrical velocity profile requires that $t_1 = 0.05$ and $t_2 = 0.45$. The total inertia is $I = 6 \times 10^{-3} + 5 \times 10^{-4} + 10^{-3} = 7.5 \times 10^{-3}$. From Table 1.5.1 we have $\omega_{max} = 10\pi / 0.4 = 69.813$ rad/s or $60\omega_{max} / (2\pi) = 666.667$ rpm. So the load will rotate at that speed for 0.4 s.

We are given that $T_d = 2$ N·m. So the maximum torque required is $T_{max} = 12.4720$ N·m and the rms average torque is $T_{rms} = 5.0924$ N·m.

1.31 The total load displacement is given as $\theta_f = 4\pi$ rad. We also have $t_f = 1$ s and a slew time of $t_2 - t_1 = 0.6$ s. Using a symmetrical velocity profile requires that $t_1 = 0.2$ and $t_2 = 0.8$. The total inertia is $I = 10^{-2} + 6 \times 10^{-4} + 2 \times 10^{-3} = 11.6 \times 10^{-3}$. From Table 1.5.1 we have $\omega_{max} = 4\pi / 0.8 = 15.7083$ rad/s or $60\omega_{max} / (2\pi) = 150$ rpm. So the load will rotate at that speed for 0.6 s.

We are given that $T_d = 0.5$ N·m. So the maximum torque required is $T_{max} = 1.4111$ N·m and the rms average torque is $T_{rms} = 0.7629$ N·m.

1.32 The equivalent inertia of the load mass is, from (1.5.11),

$$I_L = \frac{50(0.008)^2}{4\pi^2} = 8.106 \times 10^{-7}$$

The mass of the screw is

$$m_r = \rho V = 7700\pi(0.01)^2(0.7) = 1.6933 \text{ kg}$$

and the inertia of the screw is

$$I_r = \frac{1}{2} 1.6933(0.01)^2 = 8.467 \times 10^{-5}$$

So the total system inertia is

$$I = I_m + I_L + I_r = 2 \times 10^{-4} + 8.106 \times 10^{-7} + 8.467 \times 10^{-5} = 2.855 \times 10^{-4} \text{ kg} \cdot \text{m}^2$$

From the equation of motion, the required torque is $T = I\dot{\omega}$. The linear displacement x of the mass is related to the rotation angle θ of the screw by $x = L\theta / 2\pi$. Thus the linear acceleration $\ddot{x}$ is related to the angular acceleration $\ddot{\theta} = \dot{\omega}$ by $\dot{\omega} = 2\pi\ddot{x} / L$.

The given linear acceleration is $\ddot{x} = (0.3 - 0) / 0.2 = 2 = 1.5 \text{ m/s}^2$. Thus

$$\dot{\omega} = \frac{2\pi(1.5)}{0.008} = 1178.1 \text{ rad/s}^2$$

Thus the required torque is $T = 2.855 \times 10^{-4} (1178.1) = 0.3363 \text{ N} \cdot \text{m}$.

```

1.45

```
>> h=polyval([0.0125,-5,500],t);  
>> plot(t,h),xlabel('Time(s)'),ylabel('Height (m)')
```

1.46 The given parameters are m , g , h_0 , and v_0 . Follow Example 1.4.1 and program equations (1.4.3) for α and (1.4.2) for t_f .

1.47

```
t1=0:0.001:0.5;  
om1=300*t1;  
t2=0.501:0.001:2.5;  
om2=150*ones(size(t2));  
t3=2.501:0.001:3;  
om3=-300*(t3-2.5)+150;  
t=[t1,t2,t3];  
om=[om1,om2,om3];  
plot(t,om)
```

1.48 Here is a fragment of the program. You must create code to input the following parameters: θ_f , T_d , t_1 , t_2 , t_f , and I .

```
om_max=theta_f/t2  
alpha_max=theta_f/(t1*t2)  
T_max=I*theta_f/(t1*t2)+Td  
T_rms = sqrt(2*I^2*theta_f^2/(tf*t1*t2^2)+Td^2)
```

1.49

Follow Example 1.5.5. The equations are:

$$I_L = \frac{mL^2}{4\pi^2} \quad m_s = 7700\pi r^2 L$$

$$I_s = \frac{1}{2}m_s r^2 \quad I = I_m + I_L + I_s$$

$$\ddot{x} = \frac{v_s}{t_1} \quad \dot{\omega} = \frac{2\pi\ddot{x}}{L}$$

$$T = I\dot{\omega}$$
